STATISTICAL RELATIONSHIPS BETWEEN FLOW AND SALINITY

In an effort to evaluate the relationship between the amount of freshwater flow needed to maintain the salinity wedge at selected points along the NW Fork of the River, regression analyses were conducted using flow and salinity data collected from the river from January 1997 through July of 2000.

Monitoring Sites and Sampling Protocol

Historical flow data were obtained from the Lainhart Dam, located on the Loxahatchee River near Jupiter, Florida. Daily stage and flow data were obtained from the SFWMD's DBHYDRO data retrieval system for the Lainhart Dam for the period of record of January 1997 through July 2000. The collected stage data were converted to flow (cubic feet per second) using a rating curve developed by the District. This curve was developed based on a 1994 re-calibration analysis of the Lainhart Dam.

Historical flow and salinity data have been periodically collected for the Loxahatchee River and estuary since the 1970's (e.g., Rodis 1973, Chiu 1975, Russell and McPherson 1984, Mote Marine Laboratory 1990b, Dent 1997). The January 1997 – July 2000 period of record was selected because it brackets the period when recent changes were made to the river channel. Several river channels (or gaps) were created over the past 25 years to provide shorter routes for boaters. Unfortunately, these "shortcuts" bypassed historic river meander flow patterns and provided a more direct path for the upstream migration of salt water. In 1997, the Jupiter Inlet District constructed a number of earth and rock dams to seal off these short cuts and reestablish historical flow routes for the river. Salinity studies conducted by the Loxahatchee River Environmental Control District demonstrated that these construction activities resulted in lower salinity levels upstream of the closures (Dent, 1997). The 1997-2000 period of record reflects these hydrologic improvements to the river as well as the 1994 re-calibration of flow data obtained from the Lainhart Dam. This time period also includes a wide range of both high, average, and low flow periods and also corresponds to the most recent set of salinity values collected for the river by the Loxahatchee River Environmental Control District.

Historical salinity data for five river sampling sites were obtained from water quality surveys conducted by the Loxahatchee River Environmental Control District for the period of record January 1997-July 2000. Water Quality Station # 63 is located at a depth of about 3.0 meters between mid-channel and the southern shore at approximately SFWMD river mile 6.5 in the vicinity of the south boat ramp for Jonathan Dickinson State Park. This station was used previously by the U.S. Geological Survey, the SFWMD, and the Loxahatchee River Environmental Control District to record Results of the regression analyses and their associated graphical plots are presented in **Figures D-3** through **D-12**.

Results

Table D-1 and Figure D-1 provide summaries of the minimum dry season flow rates that are required to be delivered from the Lainhart Dam to the NW Fork of the Loxahatchee River to maintain a bottom salinity of 2 ppt for selected locations along the

river. These results are reported in SFWMD river miles upstream from the Jupiter inlet.

Table D-1. Relationship between Dry Season Lainhart Dam Flow and estimated position of the saltwater wedge within the Northwest Fork of the Loxahatchee River.

Water Quality Station Number	Upstream Extent of 2 ppt salinity wedge (river miles)	Dry Season discharges from Lainhart Dam (cfs)	
		Total Data Set (Jan 1997-Jul/2000)	After closure of Gaps
WQ Station # 63	6.5	203	236
Avg. of WQ Stations # 63 &64	7.1	146*	161*
WQ Station # 64	7.7	90	87
Avg. of WQ Stations # 64 & 65	8.1	68*	68*
WQ Station # 65	8.6	47	49
Avg. of WQ Stations # 65 & 66	9.0	31*	32*
WQ Station # 66	9.4	15	15**
WQ Station # 67	10.5	<10	< 10**

* = Flows shown were estimated by interpolation of data between upstream and downstream water quality sampling stations;

** Represents upper limit for this value

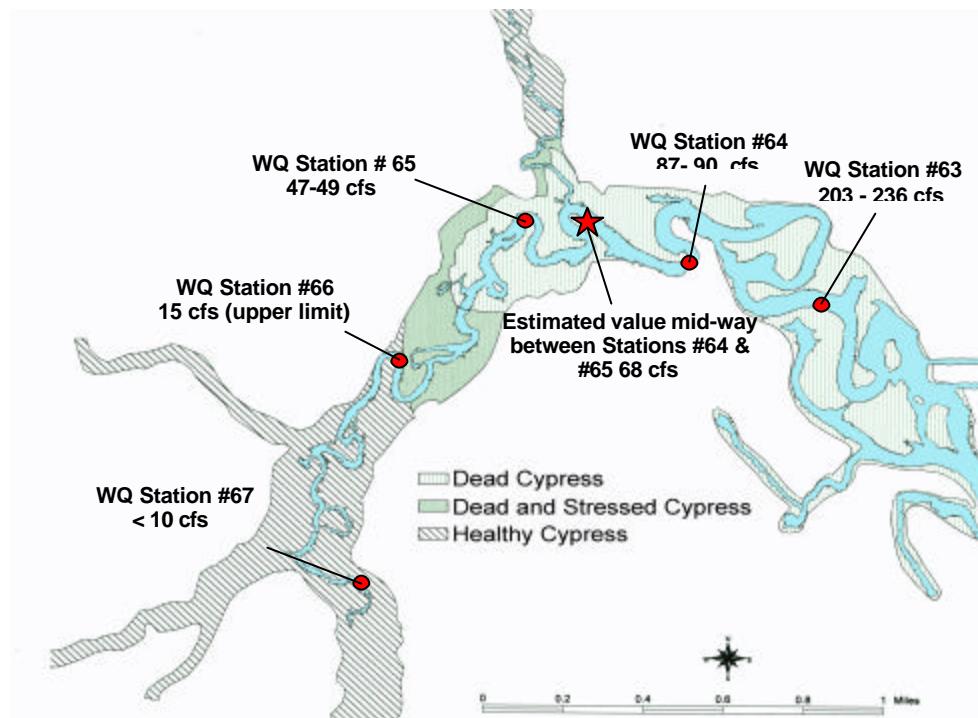

Figure D-1. Amount of flow required from Lainhart Dam to maintain river bottom salinity of 2ppt at selected sites, NW Fork, Loxahatchee River

WQ Station # 63 (River Mile 6.5)

Station # 63 (**Figure D-1**) is located just upstream from the south boat ramp in Jonathan Dickinson State Park at SFWMD river mile 6.5. This site generally represents the nearest river water quality station adjacent to the central embayment (estuary). This water quality monitoring site is directly influenced by the daily tidal cycle and upstream movement of saltwater. Over the three year period of record, daily salinity values ranged

from less than 0.4 ppt during high discharge events, to a high of 20-25 ppt recorded during a number of low flow periods. Time series for flow and salinity for each of the five river water quality sampling stations are shown in **Figures D-3 through D-12**.

Results of the regression analyses show that a flow of within the range of 203 - 236 cfs would be required from the Lainhart Dam to reduce river bottom salinity to less than 2 ppt at WQ Station # 63 (**Figure D-1**). Salinity data recorded from this site exhibited a wide degree of variability as compared to the other upstream monitoring sites. WQ Station #63 showed the poorest correlation between river flow and salinity recording an R^2 of 0.25 for the 1997-2000 data set, and 0.40 after closure of the river gaps in 1997 (**Figure D-3**). This low correlation occurs, in part, because this site is the most downstream monitoring station and is subject to greater daily tidal fluctuations, effects of wind, and major storm events due to its proximity to the ocean at the Jupiter Inlet. In addition, this area may also be subject to the cumulative effects of freshwater seepage from surrounding uplands and other inflows that are not fully accounted for in the estimated river flow.

WQ Station # 64 (River Miles 7.7)

This station is located approximately 1.2 miles upstream of Station # 63 or about 0.5 mile upstream of the Jonathan Dickinson State Park canoe concession area at river mile 7.7. Because this site is located further upstream within the NW Fork, it showed less variability among data points as compared to Site # 63 (**Figure D-3**). Seasonal salinity values range from less than 0.1 ppt (essentially freshwater) to 15 – 24 ppt during low flow periods. Review of historical data shows that significantly less river flow is required to maintain the saltwater wedge (**Table D-1**) at this site as compared to WQ Station # 63. At this location, flows within the range of 87-90 cfs are needed from the Lainhart Dam, plus another estimated 10 cfs from other upstream sources, to maintain the salinity wedge at 2 ppt. The estimated dry season flow contributions for these other upstream tributaries were estimated as: Cypress Creek (7 cfs), Kitching Creek (2 cfs), and Hobe Grove Ditch (1 cfs) based on typical dry season flow values obtained from the USGS study (Russell and McPherson, 1984). Therefore, the total amount of water needed to maintain the salinity wedge at river mile 7.7 is approximately 100 cfs. The correlation between river flow and salinity at WQ Station # 64 is greatly improved, relative to station 63, with R^2 values of 0.59 and 0.60 reported for this site (**Figure D-4**).

Confluence of NW Fork and Kitching Creek (River Mile 8.1)

River mile 8.1 is located just below the mouth of Kitching Creek about one mile downstream of the “stressed cypress zone” (**Figure D-1**). This area was selected as a point of interest because it lies just downstream of the remaining cypress river-swamp habitat that the proposed MFL is trying to protect, and it also lies just downstream of Kitching Creek, an area that still contains significant amounts of cypress swamp habitat. Because no water quality data exists for this site, an estimate was made of the amount flow that needed to delivered from the Lainhart Dam to maintain the salinity wedge at 2 ppt at river mile 8.1. Water quality and flow data from WQ Stations #64 (RM 7.7) and WQ Station #65 located further upstream at RM 8.6 were averaged together to arrive at 68 cfs as the amount of flow required to maintain the freshwater-saltwater interface at

less than 2 ppt at river mile 8.1. (e.g., $(49 \text{ cfs} + 87 \text{ cfs})/2 = 68 \text{ cfs}$).

It is important to note that during the 1940's Kitching Creek and areas located just upstream from this point in the river supported significant amounts of swamp hardwood (cypress) habitat as documented **Figure B-6 Appendix B** of this report. Interpretation of the vegetation studies conducted by Alexander and Crook (1975) show that swamp hardwoods were still the predominate vegetation cover at this point in the river in the early 1970s. Review of 1995 infrared photos (**Figure B-6, Appendix B**) shows that this same area of the river is now dominated by mangroves, most likely a response to increased salinity levels at this point in the river over the past 30 years.

WQ Station # 65 (River Mile 8.6)

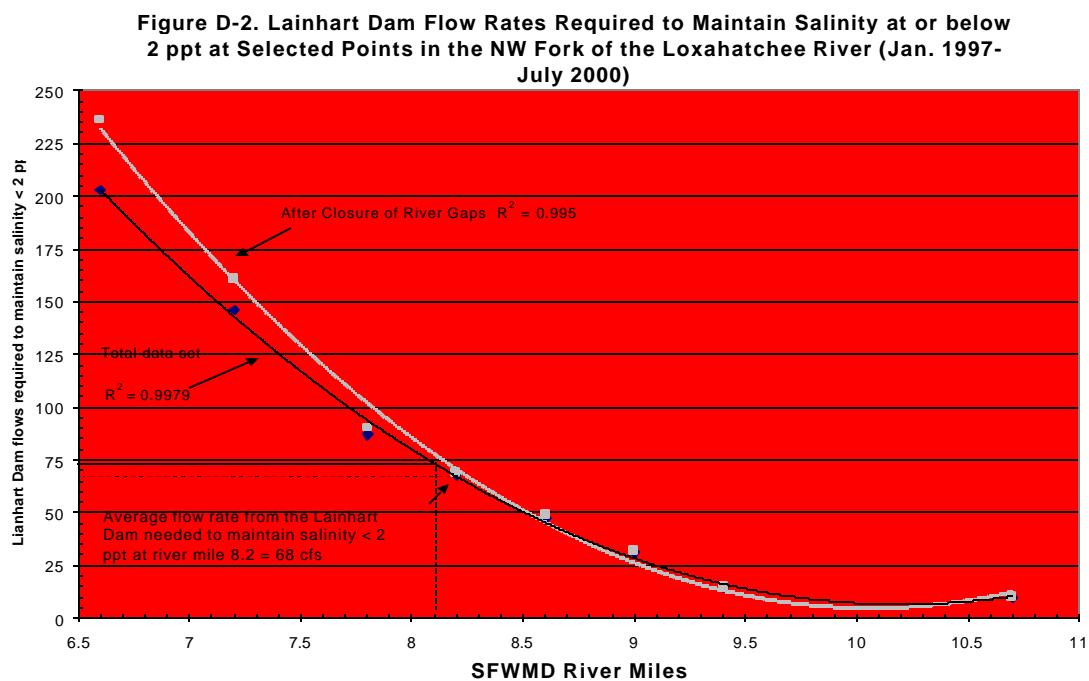

Station # 65 is located about 0.5 miles above the confluence of Kitching Creek and the NW Fork of the River, or about 0.9 mile upstream of Station # 64 at RM 8.6. Because this site is located further upstream within the NW Fork, the data shows less variability than what occurs at downstream water quality monitoring sites (**Figure D-5**). Seasonal salinity values range from less than 0.1 ppt (freshwater) to 13 – 19 ppt during low flow periods.

Results of the regression analyses indicate that flow rates within the range of 47–49 cfs are required from the Lainhart Dam to maintain salinity at or below 2 ppt at RM 8.6 (**Table D-1**). This is about 44% less flow required to maintain the salinity wedge at RM 8.6 as compared to WQ Station # 64 located 0.9 miles downstream. This is an important sampling location in that it represents the transition zone between downstream areas of the river that have been impacted by saltwater intrusion (i.e., historical bald cypress communities replaced by mangroves), and upstream areas of the river that are currently stressed by periodic exposure to saline water (**Figure D-1**).

WQ Stations # 66 & 67 (River Miles 9.4 & 10.5)

Review of water quality data collected from WQ Stations #66 (river mile 9.4) and #67 (river mile 10.5) show that during average and high flow conditions, these two sites are dominated primarily by freshwater. However during prolonged drought conditions, both of these sites have experienced the saltwater wedge to move long distances upstream within the river within relatively short time periods (days). For example, the flow/salinity relationship developed for Station # 67 (River Mile 10.5) in **Table D-1** shows that during prolonged low flow periods (flows less than 10 cfs) the saltwater wedge will penetrate upstream areas of the river as far upstream as Trapper Nelson's. Although the number of data points collected from this upstream area of the river are significantly less than the downstream monitoring sites, these data correlate well with previous salinity studies conducted on the river (e.g., Russell and McPherson 1984). Similar results are shown for WQ Station # 66 where the upper limit of 15 cfs was estimated as the required flow delivered from the Lainhart dam to maintain a salinity of less than 2 ppt at river mile 9.4 (**Figure D-1**).

Based on the statistical analysis of the flow/salinity data discussed above, **Figure D-2** provides the general relationship between the volume of water need to be delivered from the Lainhart Dam during the dry season to maintain salinity near 2 ppt at various locations (river miles) along the NW Fork of the Loxahatchee River.

Calculation of Mean Wet and Dry Season Flows to the Loxahatchee Estuary

Table D-37 provides a summary of average freshwater flows delivered to the three forks of the Loxahatchee estuary during the wet and dry seasons as well as during selected drought events. Four major sources of water (G-92 and the Lainhart Dam, Cypress Creek, Hobe Grove Ditch and Kitching Creek) provide the majority of freshwater flow to the Northwest Fork of the Loxahatchee River. Other historical inputs such as Moonshine Creek and Wilson Creek have been highly altered by drainage and development, and today only provide a very small portion of flow to the Northwest Fork of the river and are not included in the table.

Table D-37. Summary of Average Wet and Dry Season Flows to the Loxahatchee Estuary.

Tributary	Average Daily Flow (cfs)		1980-81 drought		1989-90 drought		Period of Record

¹ Wet season defined as May 15- Oct. 15; Dry season = Oct. 16- May 14

²From Russell and McPherson 1984 (POR 1980-1982)

The average wet and dry season flows for Lainhart Dam, Cypress Creek, Hobe Grove Ditch, Kitching Creek, and the C-18 Canal @ S-46 were calculated by averaging the flows recorded from May 15 to October 15 over the period of record, and from October 16 to May 14 of the following year over the period of record, respectively. In cases where the data sets were discontinuous, the averages were calculated using the information that was available. The DBHYDRO data that was available for the tributary analysis are summarized on the following tables. The average wet and dry season flows for the North Fork were taken from Russell and McPherson (1984).
